

AXPA17851

4 x 48W MOSFET
Quad Bridge Power Amplifier

Datasheet — Apr 2022

Description

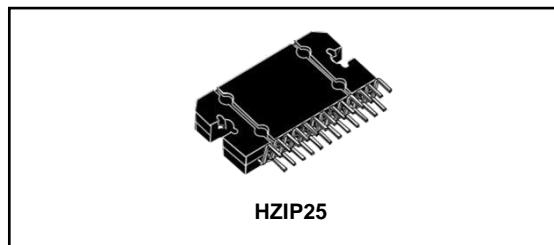

AXPA17851 is a quad bridge class AB car radio audio power amplifier designed in BCD (Bipolar, CMOS, DMOS) technology with a fully complementary P-Channel/N-Channel output structure. It has a rail to rail output voltage swing, high output current and low saturation losses, giving it an excellent distortion performance. AXPA17851 can operate down to 6V for low voltage operation to achieve 'start-stop' battery profile during engine stop enabling reduction in overall emissions.

Features

- Multipower BCD technology with DMOS MOSFET output power stage
- Hi-Fi class low distortion
- Low output noise
- High immunity to RF noise injection
- Standby function
- Mute function
- Auto-mute at min. supply voltage detection
- Low external component count
 - No external compensation
 - No bootstrap capacitors
- Internally fixed gain (26dB)
- Capable to operate down to 6V (e.g. "start-stop")
- High output power capability:
 - 4 x 48W/4Ω Max.
 - 4 x 28W/4Ω @ 14.4V, 1kHz, 10%
- Protections:
 - Output short circuit to GND, to Vs, across the load
 - Very inductive loads
 - Overrating chip temperature with soft thermal limiter
 - Output DC Offset detection
 - Output Clipping detection
 - Load dump
 - ESD

C _D THD	Clip detector THD level	V _s > 6.5V	-	2	-	%

4 Functional Description

4.1 Overview

AXPA17851 is a complementary quad audio power amplifier designed in BCD Technology. Integrated within the AXPA17851 are:

- 4 dependent class AB amplifiers with DMOS Mosfet output stages
- Clipping detector
- Offset Detection circuit with CDOD pin
- Standby function with STBY pin
- Mute function with MUTE pin
- Circuits fully operational down to 6V, with no pop noise and uninterrupted play during battery transitions.
- Protection circuits for
 - short circuit
 - open circuit
 - over voltage
 - over temperature

It is available in package HZIP25.

4.2 Inputs

AXPA17851's channel inputs are ground-compatible with reference to ACGND. Referring to application circuit (Figure 2), input capacitors of $0.1\mu F$ will attain a low frequency cut-off of around 16Hz. For best pop noise minimization, input capacitors should be 1/4 of the capacitor connected to ACGND pin.

4.3 Standby and Mute

Standby and Mute functions are controlled by CMOS compatible STBY and MUTE pins.

Control signals for these functions should be coupled to AXPA17851 using a RC circuit (refer to Figure 2 Application Diagram) to damp any sharp transition, preventing unwanted audible transient noise. If not used, an external resistive pull up to Vs should be connected.

4.4 SVR – Supply Voltage Rejection

The SVR pin is set internally to $V_s/4$ and serves as the input voltage reference as well as to generate the $V_s/2$ output reference.

An external capacitor connected to the SVR help in supply voltage ripple rejection and serves 3 functions:

1. Start-up time
2. Shut-down time
3. Pop noise free transitions.

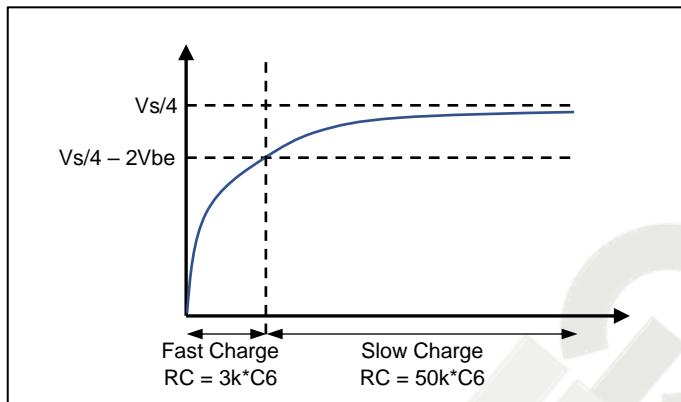

A minimum capacitance value of $10\mu F$ is recommended.

Upon STBY going beyond the 2.6V threshold, the SVR pin is charged for normal operation.

The Start-up profile time constant is determined by an internal R coupled with the external capacitor. A 2-step profile is designed with a fast charge of $3k\Omega$ from 0 to $V_s/4-2V_{be}$ voltage and thereafter a slower charge through $50k\Omega$ to $V_s/4$ voltage.

A time constant slower than $2.5V/ms$ is recommended for pop-free transitions.

Figure 4 SVR charge diagram

Proper sequencing of the MUTE and STBY can ensure no audible noise during transition. Placing the amplifier in Mute prior to the device going into or coming out from Standby will ensure no audible noise in the transition.

4.5 Operation Modes

4.5.1 Low Voltage Operation

In the effort to reduce emissions of polluting substances, OEM specifications dictates that the car engine automatically stops when the car is stopping at traffic lights. AXPA17851 can meet this operation requirement.

It provides for continuous operation when the battery falls as low as 6V, remaining fully operational. The output power is however reduced accordingly to the available voltage supply. Upon battery voltage dropping below 6V, a proper sequencing is performed with amplifier first fast muted and then the SVR capacitor discharged. On returning to above 6V, the amplifier restarts.

4.5.2 Cranks

AXPA17851 has excellent performance on worst case cranks profile from 16V to 6V, continuing to play and without producing any pop noise.

It can sustain operation for battery cranking curves shown below:

Figure 5 Battery cranking curve example 1

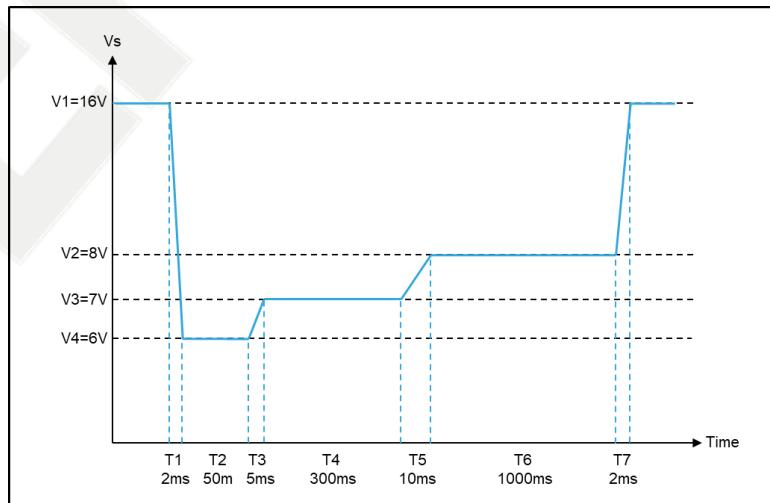

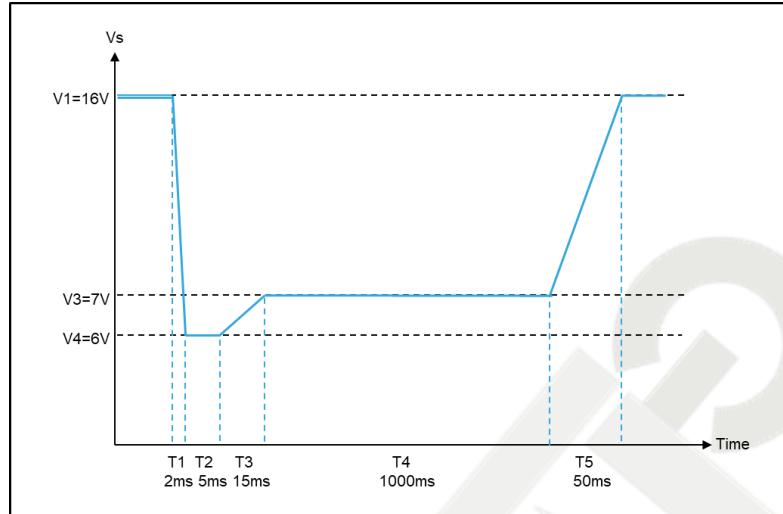

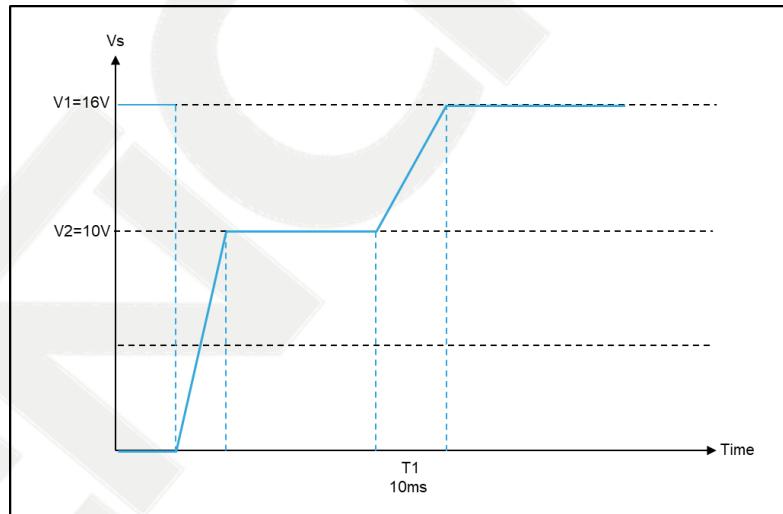

Figure 6 Battery cranking curve example 2

4.5.3 Advanced battery management (hybrid vehicles)

For sudden spikes in battery voltage, as in the case of Hybrid vehicles engine ignition, AXPA17851 can handle such situations of 16V in 10ms spikes without any pop noise and interruptions.

Figure 7 Upwards fast battery transitions diagram

4.6 Output Clip Detection (CDOD)

The CDOD indicates Output Clip Detection during non Mute operation. It goes active low upon occurrence of clipping at the output waveform. An internal clipping circuit detects for output distortion of more than 1% and pulls down CDOD low. This acts as a feedback signal for the audio processor to reduce its output signal to the amplifier for clipping reduction. Clip detection is functional down to Vs=6.5V.

4.7 Output DC Offset Detection (CDOD)

The CDOD indicates Output DC Offset Detection during Mute operation.

To safeguard against damaging speakers because of large DC offsets at the outputs, an offset detector is designed into AXPA17851. When muted and without signal input, it detects for differential output voltage, to be within a threshold of +/-2V and pulls CDOD low if it is exceeded.

4.8 Protection

4.8.1 Short circuits

AXPA17851 detects for short circuit under the conditions of:

1. Short to ground

When detected, the outputs are put into tristate high impedance. The device will only revert to normal operation when short is removed. This is determined by detecting the output voltage returning to internally set limits.

2. Short to Vs

When detected, the outputs are put into tri-state high impedance. The device will only revert to normal operation when the short is removed. This is determined by detecting the output voltage returning to internally set limits.

3. Short across the load

This is determined by sensing an over current at the outputs. The outputs are then put into a high impedance protection mode for 100 μ s. The short is repeated checked every 100 μ s. If the short is removed, the amplifier returns to normal operation, otherwise high impedance state is maintained.

4.8.2 Open circuit Operation

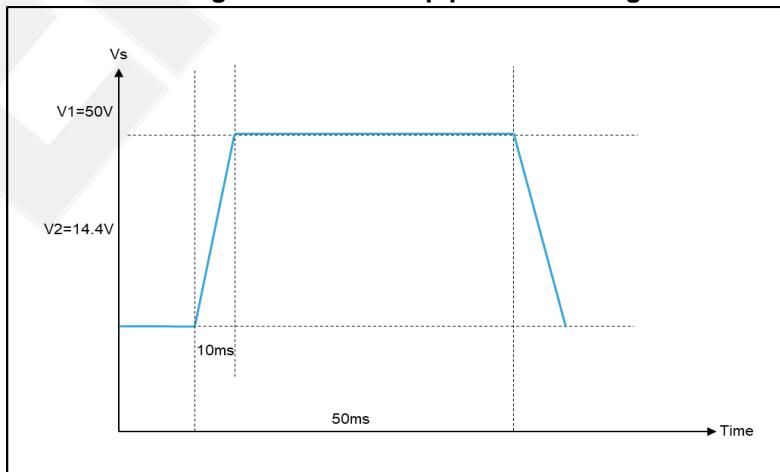

When there is an open load condition, no damage will occur. AXPA17851 will continue to play.

4.8.3 Over-voltage and load dump

AXPA17851 is designed to detect over voltage of beyond 19V. When detected, the amplifier outputs go into a high impedance state preventing damage. Normal play operations are reverted when Vs returns to the acceptable range.

The robustness of the design allows for protection against load dumps surges of as high as 50V with 5ms rise time and 50ms duration.

Figure 8 Load dump protection diagram

4.8.4 Thermal protection

Thermal warning is activated at T_j of 140°C. If T_j rise continues and reaches 150°C, a slow mute is then activated to reduce output power and dissipation. On reaching T_j of 170°C, the amplifier will be shutdown to prevent damage.

4.9 Heat sink definition

The power dissipation and temperature generated by the heat dissipation is governed by the following equation.

$$P_d * (R_{thj-case} + R_{thc-amb}) = T_j - T_a$$

P_d = Power dissipation of amplifier (W)

$R_{thj-case}$ = Thermal resistance from silicon junction to the package casing. (°C/W)

$R_{thc-amb}$ = Thermal resistance from case to ambient (°C/W)

T_j = Silicon junction operating temperature (°C)

T_{amb} = Ambient Temperature. (°C)

Example:

$P_d = 28W$

$R_{thj-case} = 1^{\circ}\text{C}/\text{W}$

$T_j = 150^{\circ}\text{C}$

$T_{amb} = 70^{\circ}\text{C}$

$R_{thc-amb} = 1.8^{\circ}\text{C}/\text{W}$

The heatsink need to be designed to have thermal resistance of 1.8°C/W or lower to avoid overheating and thermal shutdown.
